- **Abstract:**
  (EP2657867)
  A human body data matching method for medical cosmetic applications includes the step of providing a human body imaging system (1) having a digital image pickup module (11) for **scanning** and photographing human **bodies** to obtain image data, the step of rendering the image data into human digital images, the step of storing the human digital images in a databank (21), the step of fetching pre-stored storage human digital images of the person going to take an orthopedic or cosmetic surgery from the databank (21), and the step of matching the fetched human digital images to make sure the location and differences. This method prevents surgical errors due to misunderstanding in communication between the surgeon and the patient.

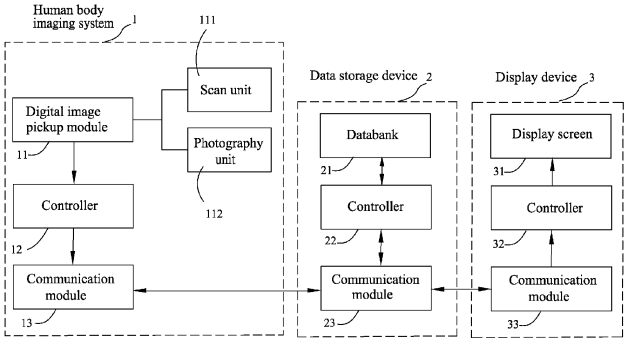

FIG. 1

Digital image storage system and human body data matching algorithm for medical aesthetic application

- **Abstract:**
  (KR20130137776)
  A human body data matching algorithm for medical aesthetic application includes the step of providing a human body image acquisition unit, the step of using the human body image acquisition unit to obtain a digital 3D image data of the body of a person during an optimal lifetime of the person, the step of storing the digital 3D image data in a data storage bank, the step of fetching the digital 3D image data from the data storage bank when going to perform a medical aesthetic surgery, and the step of matching the digital 3D image data for reference in the medical aesthetic surgery to avoid communication errors between a patient and a surgeon. [Reference numerals] (1) Human body image acquisition unit;(11) Digital 3D image sensor;(12,22,32) Controller;(13,23,33) Communication module;(2) Data storage unit;(21) Data storage bank;(3) Display unit;(31) Digital image display screen in a medical asethetic institute

- **Abstract:**
  (US8700432)
  There is provided a system for cutaneous diagnosis including a first access device. The first access device includes a camera, a processor and a display of digital body map having an anatomical marker. The camera captures image data of a lesion and the processor tags a location of the lesion captured from the camera with the anatomical marker, yielding a first record. The first record is transmitted by the first access device via a network to the first database. The first database receives and stores the first record. The second access device is in communication with the database. The second access device retrieves the first record from the database via the network and attaches physician data to the first record, thus yielding a second record. The second record is transmitted via the network to a second database and is stored therein.

Method for detecting abnormalities in medical screening

- **Abstract:**
  (US8121863)
  A computer-aided detection process for interpreting body images using knowledge based SMART algorithms. The process interprets, in real time, body scan images submitted from screening centers and other certified medical practitioners around the world, and then renders an accurate, reliable and reproducible analysis of each patient's health status relative to the specific body image submitted and returns the results to the originating source.
